REPORT ON THE CROP CUTTING SURVEY
AUTUMN (KANNI) CROP OF PADDY
IN KERALA STATE—1959.

1. *Introduction.*—Random Sample Crop-cutting experiments on Paddy are being conducted by this Department from the year 1951 onwards. This report gives a summary of the conduct of the crop-cutting survey on the autumn (September-October) crop of paddy in Kerala State during 1959, and the results therefrom. The survey covered all the Taluks of the State wherein the reference crop is cultivated.

2. *Sampling design.*—As usual the stratified multistage random sample design was adopted for the survey. The taluks formed the strata, villages the primary unit, fields the secondary unit and a square plot of side $16\frac{1}{2}$ ft. the ultimate unit of sampling. From each taluk a random sample of 6 census villages was selected and from each one of those villages 5 fields were selected at random for experimentation. From each selected fields a square plot of side $16\frac{1}{2}$ ft. was located at random and the crop therefrom was harvested, winnowed and weight of the produce noted correct to the nearest quarter of a pound.

3. *Field work.*—The harvest period of the crop ranges from August-October. The field work of the survey was carried out by the Investigators of the Statistics Department. Their work was supervised by the Statistical Inspectors and District Statistical Officers. In spite of the best efforts, only 1318 experiments could be actually conducted during the season, as against the 1530 originally planned. The drige factor for each taluk was also determined based upon actual drige experiments.

4. *Analysis of the data.*—The Analysis of the data collected was done in the office of the Director of Statistics. The area under paddy in each taluk during the season was estimated from the Land Utilisation Surveys conducted by this Department. The mean yield per acre for the state was calculated by weight ing the taluk mean yields with the corresponding acreage under paddy in the Taluks. The standard errors for the taluk mean yields and the state mean yield are also calculated. The frequency distribution of the yield rates into groups of range 200 lbs./acre are also given.

5. *Results and precision.*—The mean yield for the State for the reference crop has been estimated as 1696 lbs. of paddy per acre and this has a standard error of less than 1%. From the frequency distribution it is seen that nearly 50% of the plot yields lie between the ranges 1300-2100 lbs. of paddy per acre.

For the purpose of comparison, the area, yield rate and production of the reference crop with those of the corresponding crop in the previous year are given below:—

Year & Crop.	Area (acres.)	Yield of paddy in lbs./acre.	Total production of Rice in tons.	Percentage.
Autumn 1958	982200	1547	445500	100.0
Autumn 1959	964600	1696	479800	107.7

It has to be pointed out that rice is reckoned as 65.7% of the weight of paddy in the above calculations. It may be concluded that the yield rate has increased from 1547 to 1696 lbs of paddy/acre and the total production has increased by 7.7 % from that of the previous year.

(Sd.)

Assistant Director-in-charge.

TABLE I

Autumn (Kanni) Crop of Paddy 1959.

Statement showing the estimated mean yield per acre
and the total out-turn of rice in different taluks.
