REPORT ON THE CROP CUTTING SURVEY ON THE
CROP OF PADDY 1966.

DES
LIBRARY

013 - 194

1. Introduction

This report deals with the crop cutting survey conducted on Autumn Crop of Paddy 1966. The important aspects of the survey are explained in the following paragraphs.

2. Object of the Survey

The object of the survey was to obtain precise estimates of the taluk-wise mean yield of dry paddy/hectare and also the total production of Rice in the State during the Autumn season.

3. Period of the Survey

The survey on Autumn Crop was conducted during the months of August to October 1966.

4. Coverage

The survey on Autumn crop covered 51 taluks out of 55 taluks in the State.

5. Sampling Design

The method of sampling adopted for the survey was a stratified multi-stage random sampling as in the case of the previous year. The taluk was taken as the stratum, a census village as the first stage unit, a survey sub-division number as the second stage unit, a kandom as the third stage unit and a square plot of side 5 metres as the ultimate sampling unit. From each taluk six census villages were selected with equal probability. From each of these selected village, a systematic sample of 3 survey sub-division numbers was selected from a frame consisting of the cumulative number of wet land survey sub-divisions. In survey sub-divisions having more than one kandom, one kandom was selected for the survey by the method of simple random sampling for the crop cutting experiment, after the kandoms in the survey number were serially numbered beginning from the south-west corner and proceeding anti-clockwise.

A square plot of side 5 metres was located at random in the selected kandom. The crop in the square plot was harvested, thrashed, winnowed and weighed. A sample of grain from every 6th plot harvested was forwarded to the District Statistical Officer for conducting driage experiments for estimating loss due to driage.

6. Sampling Selection

The selection of villages in each taluk was done by the concerned District Statistical Officer and the list of selected villages was forwarded to the concerned Statistical Inspectors.

7. Field work

The field work was attended to by the Investigators under the supervision of Statistical Inspectors, Senior Research Assistants and District Statistical Officers.

Eventhough the number of experiments planned was 918, only 795 experiments could be conducted. The percentage of response being 86. The less in the number of experiments was mainly due to the failure on the part of the cultivators to inform the field staff the exact time and date of the harvest. Inspections were carried out by the officers of this Department at three stages, viz. pre-harvest, at-harvest and post-harvest stages. During the Autumn crop, 73 inspections were conducted in the pre-harvest stage and 38 at post-harvest stage. The percentage of inspection at harvest stage to total experiment conducted was 22.

8. Results

The analysis of data was done at the Head Office of the Bureau of Economics and Statistics, Trivandrum. The area under paddy in each taluk obtained from the Land Utilisation Survey was used to estimate the production figures. The final estimates are presented in the following tables.

Table .. I

Taluk-wise figures relating to the number of experiments conducted, the area under the crop, estimated mean yield of dry paddy per hectare, its standard error and out-turn of cleaned

-2-

rice are given in this table. Compared to the corresponding season of the previous year the average yield for the State and the total production of Rice during Autumn 1966 have decreased by 4% and 4.7% respectively. The decrease in yield rate was due to unfavourable rainfall conditions during the sowing season.

Table - II

Table II gives district-wise estimates of mean yield in "irrigated" plots, "chemically manured" plots, "irrigated and manured" plots and in "neither irrigated and nor manured" plots. 4.28% of the plots received irrigation, 55.09% received chemical manure alone and 16.60% received both irrigation and chemical manure. The remaining 24.03% of plots were neither irrigated nor manured.

The frequency distribution of plot yields is given in table III. The analysis of variance of plot yields is given in table IV.

Table V:- gives the result of driage experiments relating to the Autumn crop 1966 viz. the number of driage experiments conducted in each taluk and the driage ratio.

The yield rate of paddy during Autumn season in each taluk for the last 5 years are given in Table VI for the purpose of comparison.

9. Procedure of Estimation

(1) Mean yield: The mean yield of dry paddy and its standard error for each taluk are calculated by adopting the following formula:

n_i = number of cuts taken in the i th village

($i = 1, 2, \dots, k$, where k is the number of villages selected in the taluk)

x_{ij} = weight of paddy taken from the j th cut in the i th village/kara ($j=1, 2, \dots, n_i$)

Taluk mean = $\bar{x} = \frac{1}{k} \sum_{i=1}^k \frac{\sum_{j=1}^{n_i} x_{ij}}{\sum_{i=1}^k n_i}$

Each cut is taken from $(\frac{1}{400})^{th}$ of the hectare.

Mean yield of dry paddy in Kg./Hect. = $\bar{x} \times 400 \times d$ where d is the driage ratio of dry paddy to wet paddy.

(ii) Standard Error (S.E.) of the taluk mean yield.

A = Mean square within karas

B = Mean square between karas

N = Total number of experiments ($\sum_{i=1}^k n_i$) in the taluk.

n_i = Number of experiments in the i th village/kara.

let $m = \frac{N^2 - \sum n_i^2}{N(k-1)}$ where k is the number of the villages selected in the taluk.

Variance of the taluk mean yield = $\frac{A}{N} + \frac{B-A}{m} \times \frac{\sum n_i^2}{N^2}$

The standard error (S.E.) is the square root of this variance. ~~With~~ The S.E. in Kg./Hect. is obtained by multiplying this root of variance with 400.

(iii) Standard Error of the State mean yield:

If a_i is the area under the crop in the i th taluk and S_i the S.E. of the estimate in the Taluk.

S.E. for the State Mean Yield = $\sqrt{\frac{\sum (a_i S_i)^2}{(\sum a_i)^2}}$

10. The weight of cleaned rice is reckoned as 65.7% of dry paddy and accordingly the total production of Rice during Autumn season was estimated at 498388 tonnes.

11. In Alleppey and Palghat Districts both State series and I.A.D.P. series of experiments were conducted during the season under report. The results obtained from the two series of experiments were pooled together and the pooled mean yield of dry paddy/hectare was calculated. The pooled average yield of dry paddy during the Autumn crop 1966 in Alleppey and Palghat Districts were ¹⁴⁵⁴ 1438 Kg./Hect. and ²⁵²⁶ 2534 Kg./Hect. respectively. The average yield estimated from the State series of experiments alone for Alleppey and Palghat districts were 1514 Kg./Hect. and 2517 Kg./Hect. respectively.

The production of Rice during Autumn 1966 as per the pooled estimate is 20822 tonnes in Alleppey District and 191297 tonnes in Palghat District. The corresponding figures obtained through

State series are 21689 tonnes in Alleppey and 190658 tonnes in Palghat. The State production as per the pooled estimate was 498160 tonnes of Rice.

For the purpose of comparison of the estimates of area under paddy, yield rate and production of cleaned Rice during the different seasons of the past five years are given in the statement A.

Trivandrum,
31--3--1967

N.GOPALAKRISHNAN NAIR,
Additional Director.
